Accomplishments

Motor Power

The problem with getting enough power to Yano's motors has been resolved. For time constraint purposes, we chose to stack multiple TC4424 H-Bridges in parallel. This allows the motors to draw as much current as they want to. Although the motors will work and not get stuck running off of only 2 H-Bridges, 3 in parallel let them move much faster and more reliably.

Yano Emotions

We created the presets for Yano's emotions. We had pretty good success with being convincing on most of the emotions. Some of the more angry emotions are quite hard to create on Yano's face because he is naturally smiling and happy. The biggest problems we had were with consistency of the expressions over time and speed of creating the expressions. To deal with consistency, we let the eye motors draw more power by adding an additional bridge before them, and by doing a lot of tweaking on the eye motor software control. The additional power to the eye motors helped with the speed of creating the expressions some, but we have mostly dealt with this by adding the ability to reverse the eye motor's direction if it is a shorter path.

Eye Motor Tweaking

The problem with Yano's eyes is that they have the largest movement range and therefore take the longest and are most easily gotten out of sync during runtime. To compare, the eyes usually have around 55 pulses to make a complete cycle, whereas the cheeks have 5 pulses and the mouth has 3. The first thing we noticed was that the pulses pulsed faster during runtime than during calibration. This could cause inconsistencies between calibration settings and runtime settings because of the difference in "spin down" time between pulses. We added a little software delay into the runtime control, not noticeable when watching, but enough to keep the runtime in sync with calibration. The next problem we that we wanted to be able to reverse the eye motor if needed to take the shortest path to its destination (we can do this because the eye motor, unlike the others, has no limits and can always run in either direction). We created special procedures for the eye motors that would allow them to wrap around past MAX to 0 and past 0 to MAX in the other direction. When we did this, however, switching directions would

cause the eye motor to get out of sync and not end up at its calibrated values. We found that, because of the hardware in Yano, when the direction is reversed, it takes a few pulses to the motors before the gears are actually moved and the eyes actually move. We accounted for this in the software, and now have a good consistent, fast control over Yano's eye motors.

Parameterized Expressions

We have taken a good look at the parameterized expressions page for Yano. The goal was to come up with a translation from the Expression Variables (valence, arousal, and stance) to the Motor Variables (eyes, cheeks, mouth). We played with many different functions, from linear to quadratic and exponential, along many axes. We did notice some good correlations between the expression variables and the motor variables that indicated this translation was possible. However, we had a couple big problems. One, the non-linear nature of the eye motors would make it nearly impossible to have any kind of functional translation map from the expression variables to this motor variable. And two, the very low resolution of the other two motors (5 values for the cheeks and 3 for the mouth) would mean a lot of significant error just from rounding problems when getting values for these motors from the expression variables. Taking into consideration these problems and the goal of our project to be more visually convincing than mathematically accurate to the expressions graph of valence, arousal, and stance, we decided a slightly different method would be appropriate. Basically, we took random input from the expression variables, and produced random output in the motor variables, with no functional correlation, but with a one to one mapping of every possible input to every possible output. This provides us with the convincing emotions on Yano while still having parameterized control of him.

Sound Analysis Software

We got the mouth to move "realistically" with speech by adding oscillation to our algorithm. For nearly all sound clips, this makes the lip sync look more realistic because the mouth is constantly moving. There are still three stages of openness, but the mouth will oscillate between them depending on the intensity. One drawback is that this doesn't allow the mouth to be motionless if the speech is one constant tone - certainly a rare situation - but the oscillation does give it a "vibrato" effect.

The three intensity regions now scale to the maximum intensity of a sound file because many sound files are recorded differently, and one definition of "loud" may apply to one sound file, and not to another. For example, now "silent" is defined as between zero and 3 percent of the maximum intensity.

We also did some tweaking based on what we feel looks the best. Adding a slight delay to the speech makes the mouth look more in sync. Also, we tweaked the percentages of the three intensity regions until we were satisfied with the values.

Time Schedule

We are reaching the end of our project, and everything seems to be coming together well. We have finished all the software and hardware implementation stages, and now we are focused on tweaking and testing our Yano control software so that everything fits together and is as realistic as possible. Other than tweaking, testing, and putting everything back together, the only thing we have left to do is prepare the final communication for our project.

Goals for the Next Two Weeks

Printed Circuit Board

We are currently in contact with the EE department at TAMU and are evaluating the possibility of having them produce a printed circuit board for our Yano Control Board. We would need this to be done early next week if we are going to be able to use it. Otherwise, we will want to solder it to a solder board next week.

Finalizing of Expression Presets

With the recent changes to the eye motor control and power, we need to take some time to modify and finalize our emotion presets and make sure they are as convincing as can be.

Finalizing of Sound Analysis Software

Over the next few weeks we plan on additional testing of the code, bug fixing, and documentation. One possibility is to add random eye movements during speech to reduce monotony.

Re-assemble Yano

Once the hardware is finalized, we need to enclose it all in his body and reassemble the body with the head on top. We will want to get this done next week.

Final Communication

As we finish up the final touches and testing of our project, we also need to begin writing the final report along with any necessary implementation notes and user manuals required for our project.
